

## Exercise 4: Financial Forecasting

### Scenario:

You are developing a financial forecasting tool that predicts future values based on past data.

### Steps:

#### 1. Understand Recursive Algorithms:

- Explain the concept of recursion and how it can simplify certain problems.

#### 2. Setup:

- Create a method to calculate the future value using a recursive approach.

#### 3. Implementation:

- Implement a recursive algorithm to predict future values based on past growth rates.

#### 4. Analysis:

- Discuss the time complexity of your recursive algorithm.
- Explain how to optimize the recursive solution to avoid excessive computation.

### 1. Understand Recursive Algorithms:

#### ✓ What is Recursion?

- **Recursion** is when a method **calls itself** with smaller inputs until reaching a **base case**.
- It simplifies problems that can be broken into smaller versions of the same problem.

#### ✓ Why is recursion useful here?

- Financial projections often follow a pattern:

$$\text{futureValue}(\text{year}) = \text{futureValue}(\text{year}-1) * (1 + \text{growthRate})$$

- Instead of using loops, recursion lets us directly state the math:

**“Future value at year depends on the value of year-1”**

### 2. Setup:

#### Create a method:

```
double calculateFutureValue(double presentValue, double growthRate, int years)
```

**Present Value:** Starting amount.

**growthRate:** Yearly rate (e.g. 0.05 for 5%).

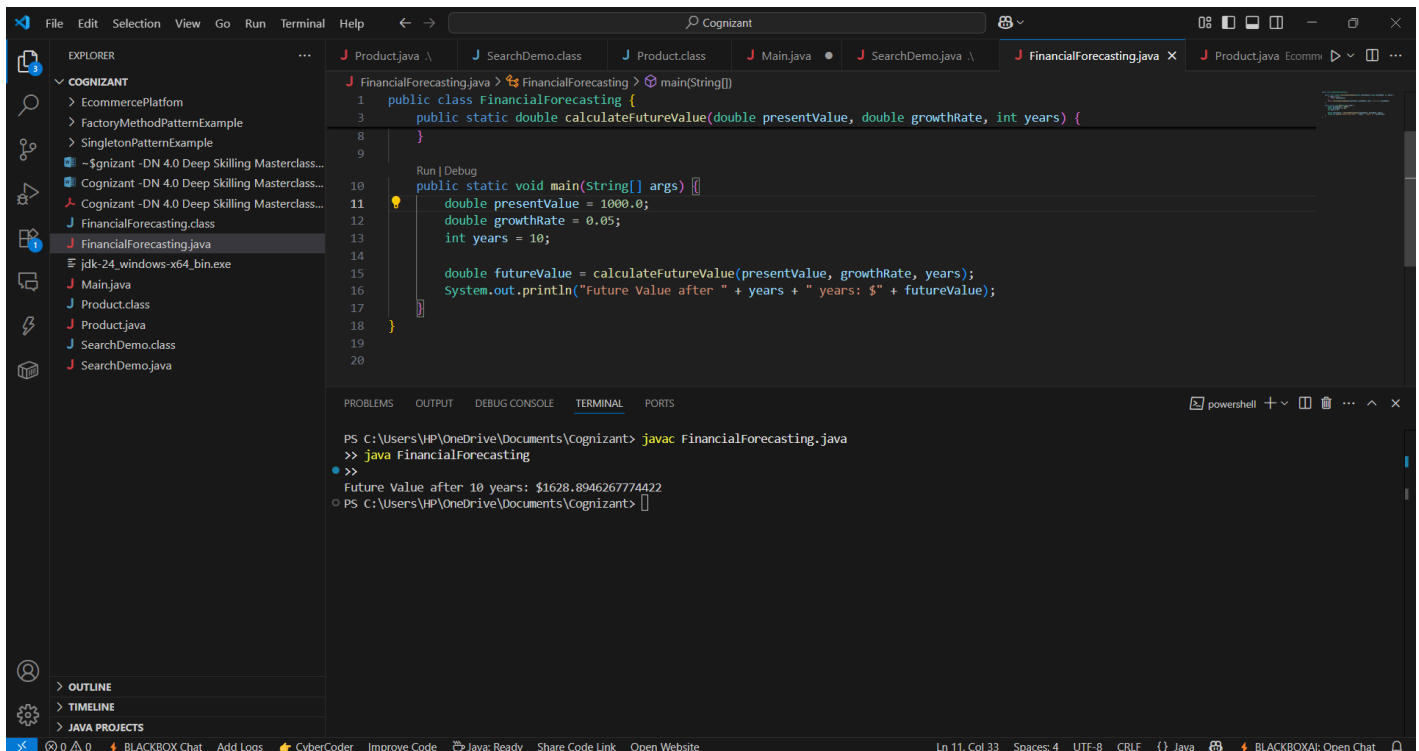

**years:** Time horizon.

### 3. Implementation:

#### Financial Forecasting.java

```
public class FinancialForecasting {  
  
    public static double calculateFutureValue(double presentValue, double growthRate, int years) {  
  
        if (years == 0) {  
  
            return presentValue;  
  
        }  
  
        return calculateFutureValue(presentValue, growthRate, years - 1) * (1 + growthRate);  
  
    }  
  
    public static void main(String[] args) {  
  
        double presentValue = 1000.0;  
  
        double growthRate = 0.05;  
  
        int years = 10;  
  
        double futureValue = calculateFutureValue(presentValue, growthRate, years);  
  
        System.out.println("Future Value after " + years + " years: $" + futureValue);  
  
    }  
  
}
```

## OUTPUT:

The screenshot shows an IDE with the following code in `FinancialForecasting.java`:

```
1 public class FinancialForecasting {
2     public static void main(String[] args) {
3         public static double calculateFutureValue(double presentValue, double growthRate, int years) {
4             // ... (code is partially obscured)
5         }
6     }
7 }
```

The terminal output shows the command `javac FinancialForecasting.java` and the execution of `java FinancialForecasting`, resulting in the output: `Future Value after 10 years: $1628.8946267774422`.

## 4. Analysis:

### Time Complexity

**Recursive call depth** = years.

Time complexity = **O(years)** because the method is invoked once per year.

Space complexity = **O(years)** due to the recursive call stack.

## 4. Optimize:

### Iterative Approach

Replace recursion with a simple for loop to save stack space:

```
double value = presentValue;
for (int i = 0; i < years; i++) {
    value *= (1 + growthRate);
}
```

Time complexity = **O(years)**

Space complexity = **O(1)**

### Direct formula (Closed-form)

Financial math formula:

$$\text{Future value} = \text{presentValue} * (1 + \text{growthRate})^{\text{years}}$$

Calculate this in **O(1)** time:

```
double futureValue = presentValue * Math.pow(1 + growthRate, years);
```

| Approach  | Time Complexity   | Space Complexity  | Best Use  |
|-----------|-------------------|-------------------|-----------|
| Recursion | $O(\text{years})$ | $O(\text{years})$ | Learning  |
| Iteration | $O(\text{years})$ | $O(1)$            | Practical |
| Formula   | $O(1)$            | $O(1)$            | Optimal   |
